

Enterprise Digital Infrastructure – Mail Lab Notes

May 26, 2026

1. Send email messages to your account on the virtual machine. Connect to the MTA running on the virtual machine using the **telnet** command on port 25 and send the appropriate SMTP commands to send a message. In the meantime, capture and analyze the traffic using Wireshark.

To check whether the messages reached your mailbox, login into the virtual machine and use the **mutt** command. You can also check the log of the mail server (**/var/log/maillog**).

2. Repeat the same experiments by exploiting spoofing mechanisms.
3. Test the DSN notification mechanism.
4. Send email messages to your gmail account.
